

Section 1.1-1.6

Work practice problems

- mechanics, stats

- newtons laws

- two new units of measurement

- Develop procedures for numerical calculations

SI $\rightarrow$ international system

SI

What is mechanics?

What happens to a "body" when a force is applied

extremely small deformation

rigid body

We study any body at rest (Static) or in motion (Dynamic)

- rigid body
 - deformable body
 - fluid
- } different mechanics

Statics vs dynamics

deals with
body at
rest or in
constant
motion

deals with
body in accel
eration

we will be dealing
with static rest

types of forces encountered

- Self weight *static*
- vehicles
- people *static*
- wind *dynamic*
- waves *dynamic*
- seismic activity *dynamic*

Basic Quantities

- ① Length point in space
- ② Time statistics is time independent
- ③ Mass not Force
- ④ Force vector quantity, Push or pull

Particle: body of negligible dimension

- can be analyzed as a point mass
- geometry is not considered in analysis

$$W = m \cdot g$$

$$5 \text{ kg} \quad g = 9.81 \text{ m/s}^2$$

Forces are concurrent
(the lines of action of all forces intersect at a common point)

rigid body

Forces are not
Concurrent

Forces either
external or internal

Cannot idealiz as a
particle

Concentrated force
acts on a point on
the body

Newton's Laws of motion

- ① a particle will remain at rest or continue to move in a straight line at constant velocity
- ② a body with unbalanced force will experience acceleration in the direction of the force
- ③ for every action there is an equal and opposite reaction
